Ascending Sort:- list_name.sort(), string_name.sort()
Descending Sort:- list.sort(reverse = True)
Min & max:- Works the same way they do in cpp, and also works on iterators
For example max(arr) returns the max element of the array.
Square root:- math.sqrt() or n**0.5 performs the same thing as well.
len():- accepts an iterator inside its parentheses
Pop:- works with list and not with string or tuples, it also works with dictionary but has to give the key.
To assign one list to another don't simply use
Ls1 = ls2
Both points to the same list
Instead use
Ls1 = ls2.copy()
Map or Dict:-
To find whether key exists or not write
If key in dict:
Or use
Dict_name.get(key,0); it returns values if exists if not then 0. If 0 is not written then it returns None.
Int to string: use str(num)
Sort a vector of pairs with first ascending and second descending or something like that:-
Ceil and floor:- math.ceil(), math.floor()
Slicing:- iterable_object[start:end:step]
Always be careful while dividing two integers when to use // and when to use /.
Also be careful to handle 32 bit integers since python integers have no limits.
